A transformer bushing is an insulating structure that facilitates the passage of an energized, current-carrying conductor through the grounded tank of the transformer. The conductor may be built in to the bushing, i.e., a bottom-connected bushing, or the bushing may be built with the provision for a separate conductor to be drawn through its centre, a.k.a., a draw-lead or draw-rod bushing.

The bushings used for transformers having voltages above 36 kV are either oil filled or capacitor type. The oil filled bushing consists of a hollow two-part porcelain cylinder with a conductor, usually a cylinder, passing through its axis. The space between the conductor and the inner surface of the porcelain is filled with oil.

The measurement of the insulation resistance in the bushings is not simple, since the bushing and the winding of the transformer should be independent; nevertheless, the measurement must be made the best way possible. The measurement of the tan δ is also difficult, since the bushings should be separated from the transformer in most cases.
